The involvement of epidermal growth factor receptors in crypt proliferation and mucosal repair was investigated in rat distal colon. The number of specific binding sites was higher in the proliferative (crypt) than in the nondividing (surface) compartment of the mucosa. A marked increase in the concentration of epidermal growth factor receptors was observed after 4 days' exposure to 3 or 6% DSS. The administration of a single oral dose of 3 mg EGF per kg per day for 3 days did not restore receptor concentrations in the proliferative compartment but increased receptor concentrations significantly in the nondividing compartment. The administration of 5 mg EGF per kg per day for 5 days restored receptor concentrations to the values observed in the untreated animals. These data indicate that the enhanced crypt proliferation is at least in part mediated by the EGF receptors. It was also shown that the increased production of mucosal growth in the colitis model is mediated by increased EGF receptor concentrations in the crypt compartment of the mucosa.The Denver Broncos will be without a key piece of their running game against the Arizona Cardinals in running back C.J.
